## 1 INTRODUCTION

tbd

## 2 PRELIMINARY

### 2.1 Basic Notations

*Point and multi-point functions.* Given a domain size  $N$  and Abelian group  $\mathbb{G}$ , a point function  $f_{\alpha,\beta} : [N] \rightarrow \mathbb{G}$  for  $\alpha \in [N]$  and  $\beta \in \mathbb{G}$  evaluates to  $\beta$  on input  $\alpha$  and to  $0 \in \mathbb{G}$  on all other inputs. We denote by  $\hat{f}_{\alpha,\beta} = (N, \mathbb{G}, \alpha, \beta)$  the representation of such a point function. A multi-point function  $f_{A,B} : [N] \rightarrow \mathbb{G}$  for  $A = (\alpha_1, \dots, \alpha_t) \in [N]^t$  and  $B = (\beta_1, \dots, \beta_t) \in \mathbb{G}^t$  evaluates to  $\beta_i$  on input  $\alpha_i$  for  $1 \leq i \leq t$  and to  $0$  on all other inputs. Denote  $\hat{f}_{A,B}(N, \mathbb{G}, A, B)$  the representation of such a point function.

**Enote:** MPF. Also representation of groups.

### 2.2 Distributed Multi-Point Functions

**Enote:** should directly adapt to multi-point function case

We begin by defining a slightly generalized notion of distributed point functions (DPFs), which accounts for the extra parameter  $\mathbb{G}'$ .

**DEFINITION 1** (DPF [1, 3]). A (2-party) distributed point function (DPF) is a triple of algorithms  $\Pi = (\text{Gen}, \text{Eval}_0, \text{Eval}_1)$  with the following syntax:

- $\text{Gen}(1^\lambda, \hat{f}_{\alpha,\beta}) \rightarrow (k_0, k_1)$ : On input security parameter  $\lambda \in \mathbb{N}$  and point function description  $\hat{f}_{\alpha,\beta} = (N, \mathbb{G}, \alpha, \beta)$ , the (randomized) key generation algorithm  $\text{Gen}$  returns a pair of keys  $k_0, k_1 \in \{0, 1\}^*$ . We assume that  $N$  and  $\mathbb{G}$  are determined by each key.

<https://doi.org/tbd>

- $\text{Eval}_i(k_i, x) \rightarrow y_i$ : On input key  $k_i \in \{0, 1\}^*$  and input  $x \in [N]$  the (deterministic) evaluation algorithm of server  $i$ ,  $\text{Eval}_i$  returns  $y_i \in \mathbb{G}$ .

We require  $\Pi$  to satisfy the following requirements:

- **Correctness:** For every  $\lambda$ ,  $\hat{f} = \hat{f}_{\alpha,\beta} = (N, \mathbb{G}, \alpha, \beta)$  such that  $\beta \in \mathbb{G}$ , and  $x \in [N]$ , if  $(k_0, k_1) \leftarrow \text{Gen}(1^\lambda, \hat{f})$ , then

$$\Pr \left[ \sum_{i=0}^1 \text{Eval}_i(k_i, x) = f_{\alpha,\beta}(x) \right] = 1$$

- **Security:** Consider the following semantic security challenge experiment for corrupted server  $i \in \{0, 1\}$ :

- (1) The adversary produces two point function descriptions  $(\hat{f}^0 = (N, \mathbb{G}, \alpha_0, \beta_0), \hat{f}^1 = (N, \mathbb{G}, \alpha_1, \beta_1)) \leftarrow \mathcal{A}(1^\lambda)$ , where  $\alpha_i \in [N]$  and  $\beta_i \in \mathbb{G}$ .
- (2) The challenger samples  $b \leftarrow \{0, 1\}$  and  $(k_0, k_1) \leftarrow \text{Gen}(1^\lambda, \hat{f}^b)$ .
- (3) The adversary outputs a guess  $b' \leftarrow \mathcal{A}(k_i)$ .

Denote by  $\text{Adv}(1^\lambda, \mathcal{A}, i) = \Pr[b = b'] - 1/2$  the advantage of  $\mathcal{A}$  in guessing  $b$  in the above experiment. For every non-uniform polynomial time adversary  $\mathcal{A}$  there exists a negligible function  $\nu$  such that  $\text{Adv}(1^\lambda, \mathcal{A}, i) \leq \nu(\lambda)$  for all  $\lambda \in \mathbb{N}$ .

We will also be interested in applying the evaluation algorithm on all inputs. Given a DPF  $(\text{Gen}, \text{Eval}_0, \text{Eval}_1)$ , we denote by  $\text{FullEval}_i$  an algorithm which computes  $\text{Eval}_i$  on every input  $x$ . Hence,  $\text{FullEval}_i$  receives only a key  $k_i$  as input.

### 2.3 Batch Codes

combinatorial/probabilistic batch codes, with cuckoo hashing a concrete instantiation

### 2.4 Oblivious Key-Value Stores

**DEFINITION 2** (OKVS[2, 4]). An Oblivious Key-Value Stores (OKVS) scheme is a pair of randomized algorithms  $(\text{Encode}_r, \text{Decode}_r)$  with respect to a statistical security parameter  $\lambda_{\text{stat}}$  and a computational security parameter  $\lambda$ , a randomness space  $\{0, 1\}^k$ , a key space  $\mathcal{K}$ , a value space  $\mathcal{V}$ , input length  $n$  and output length  $m$ . The algorithms are of the following syntax:

- $\text{Encode}_r(\{(k_1, v_1), (k_2, v_2), \dots, (k_n, v_n)\}) \rightarrow P$ : On input  $n$  key-value pairs with distinct keys, the encode algorithm with randomness  $r$  in the randomness space outputs an encoding  $P \in \mathcal{V}^m \cup \perp$ .
- $\text{Decode}_r(P, k) \rightarrow v$ : On input a (nonempty) encoding from  $\mathcal{V}^m$  and a key  $k \in \mathcal{K}$ , output a value  $v$ .

We require the scheme to satisfy

- **Correctness:** For every  $S \in (\mathcal{K} \times \mathcal{V})^n$ ,  $\Pr_{r \leftarrow \{0, 1\}^k} [\text{Decode}_r(S) = \perp] \leq 2^{-\lambda_{\text{stat}}}$ .

- **Obliviousness:** For any distinct key sets  $\{k_1^0, k_2^0, \dots, k_n^0\}$  and  $\{k_1^1, k_2^1, \dots, k_n^1\}$  that are different, if they are paired with random values then their encodings are computationally indistinguishable, i.e.,

$$\{r, \text{Encode}_r(\{(k_1^0, v_1), \dots, (k_n^0, v_n)\})\}_{v_1, \dots, v_n \leftarrow \mathcal{V}, r \leftarrow \{0,1\}^\kappa} \\ \approx_c \{r, \text{Encode}_r(\{(k_1^1, v_1), \dots, (k_n^1, v_n)\})\}_{v_1, \dots, v_n \leftarrow \mathcal{V}, r \leftarrow \{0,1\}^\kappa}$$

TBD: concrete instantiations (polynomial, sparse matrix). mention some connections to cuckoo hashing

### 3 NEW DMPF CONSTRUCTIONS

#### 3.1 Big-State DMPF

display the big-state DMPF (plus distributed gen)

#### 3.2 Batch-Code DMPF

display the batch-code DMPF

#### 3.3 OKVS-based DMPF

display the OKVS-based DMPF (plus distributed gen)

#### 3.4 Comparison

Comparison table dependent to PRG & F-MUL (list the formulas?)  
analyze tradeoff  
distributed gen advantage

### 4 APPLICATIONS

#### 4.1 PCG for OLE from Ring-LPN

Characterize parameters  
show nonregular optimization  
plug in new DMPF and show overall optimization

#### 4.2 PSI-WCA

plug in new DMPF and analyze advantage interval  
plug in distributed gen

#### 4.3 Heavy-hitters

private heavy-hitter  
or parallel ORAM?
