1 INTRODUCTION

tbd

2 PRELIMINARY

2.1 Basic Notations

Point and multi-point functions. Given a domain size N and Abelian group \mathbb{G} , a point function $f_{\alpha,\beta}:[N]\to\mathbb{G}$ for $\alpha\in[N]$ and $\beta\in\mathbb{G}$ evaluates to β on input α and to $0\in\mathbb{G}$ on all other inputs. We denote by $\hat{f}_{\alpha,\beta}=(N,\hat{\mathbb{G}},\alpha,\beta)$ the representation of such a point function. A t-point function $f_{A,B}:[N]\to\mathbb{G}$ for $A=(\alpha_1,\cdots\alpha_t)\in[N]^t$ and $B=(\beta_1,\cdots,\beta_t)\in\mathbb{G}^t$ evaluates to β_i on input α_i for $1\leq i\leq t$ and to 0 on all other inputs. Denote $\hat{f}_{A,B}(N,\hat{\mathbb{G}},t,A,B)$ the representation of such a t-point function. Call the collection of all t-point functions for all t multi-point functions.

Enote: MPF. Also representation of groups.

2.2 Distributed Multi-Point Functions

Enote: should directly adapt to multi-point function case

We begin by defining a slightly generalized notion of distributed point functions (DPFs), which accounts for the extra parameter \mathbb{G}' . Yaxin: What is \mathbb{G}' ?

Definition 1 (DPF [3, 6]). A (2-party) distributed point function (DPF) is a triple of algorithms $\Pi = (Gen, Eval_0, Eval_1)$ with the following syntax:

Gen(1^λ, f̂_{α,β}) → (k₀, k₁): On input security parameter λ ∈ N
 and point function description f̂_{α,β} = (N, Ĝ, α, β), the (randomized) key generation algorithm Gen returns a pair of keys

Conference acronym 'XX, tbd, tbd

© tbd Association for Computing Machinery. ACM ISBN tbd...\$15.00 https://doi.org/tbd $k_0, k_1 \in \{0, 1\}^*$. We assume that N and \mathbb{G} are determined by each key.

• Eval_i $(k_i, x) \rightarrow y_i$: On input key $k_i \in \{0, 1\}^*$ and input $x \in [N]$ the (deterministic) evaluation algorithm of server i, Eval_i returns $y_i \in \mathbb{G}$.

We require Π to satisfy the following requirements:

• Correctness: For every λ , $\hat{f} = \hat{f}_{\alpha,\beta} = (N, \hat{\mathbb{G}}, \alpha, \beta)$ such that $\beta \in \mathbb{G}$, and $x \in [N]$, if $(k_0, k_1) \leftarrow \text{Gen}(1^{\lambda}, \hat{f})$, then

$$\Pr\left[\sum_{i=0}^{1} \mathsf{Eval}_{i}(k_{i}, x) = f_{\alpha, \beta}(x)\right] = 1$$

 Security: Consider the following semantic security challenge experiment for corrupted server i ∈ {0, 1}:

(1) The adversary produces two point function descriptions $(\hat{f}^0 = (N, \hat{\mathbb{G}}, \alpha_0, \beta_0), \hat{f}^1 = (N, \hat{\mathbb{G}}, \alpha_1, \beta_1)) \leftarrow \mathcal{A}(1^{\lambda})$, where $\alpha_i \in [N]$ and $\beta_i \in \mathbb{G}$.

(2) The challenger samples $b \leftarrow \{0,1\}$ and $(k_0,k_1) \leftarrow \text{Gen}(1^{\lambda},\hat{f}^b)$.

(3) The adversary outputs a guess $b' \leftarrow \mathcal{A}(k_i)$.

Denote by $\operatorname{Adv}(1^{\lambda}, \mathcal{A}, i) = \Pr[b = b'] - 1/2$ the advantage of \mathcal{A} in guessing b in the above experiment. For every non-uniform polynomial time adversary \mathcal{A} there exists a negligible function v such that $\operatorname{Adv}(1^{\lambda}, \mathcal{A}, i) \leq v(\lambda)$ for all $\lambda \in \mathbb{N}$.

Definition 2 (DMPF). A (2-party) distributed multi-point function (DMPF) is a triple of algorithms $\Pi = (\text{Gen}, \text{Eval}_0, \text{Eval}_1)$ with the following syntax:

• Gen $(1^{\lambda}, \hat{f}_{A,B}) \to (k_0, k_1)$: On input security parameter $\lambda \in \mathbb{N}$ and point function description $\hat{f}_{A,B} = (N, \hat{\mathbb{G}}, t, A, B)$, the (randomized) key generation algorithm Gen returns a pair of keys $k_0, k_1 \in \{0, 1\}^*$.

Eval_i(k_i, x) → y_i: On input key k_i ∈ {0, 1}* and input x ∈ [N] the (deterministic) evaluation algorithm of server i, Eval_i returns y_i ∈ G.

We require Π to satisfy the following requirements:

• Correctness: For every λ , $\hat{f} = \hat{f}_{\alpha,\beta} = (N, \hat{\mathbb{G}}, \alpha, \beta)$ such that $\beta \in \mathbb{G}$, and $x \in [N]$, if $(k_0, k_1) \leftarrow \text{Gen}(1^{\lambda}, \hat{f})$, then

$$\Pr\left[\sum_{i=0}^{1} \mathsf{Eval}_{i}(k_{i}, x) = f_{\alpha, \beta}(x)\right] = 1$$

 Security: Consider the following semantic security challenge experiment for corrupted server i ∈ {0, 1}:

(1) The adversary produces two t-point function descriptions $(\hat{f}^0 = (N, \hat{\mathbb{G}}, t, A_0, B_0), \hat{f}^1 = (N, \hat{\mathbb{G}}, t, A_1, B_1)) \leftarrow \mathcal{A}(1^{\lambda}),$ where $\alpha_i \in [N]$ and $\beta_i \in \mathbb{G}$.

(2) The challenger samples $b \leftarrow \{0, 1\}$ and $(k_0, k_1) \leftarrow \text{Gen}(1^{\lambda}, \hat{f}^b)$.

(3) The adversary outputs a guess $b' \leftarrow \mathcal{A}(k_i)$.

Denote by $Adv(1^{\lambda}, \mathcal{A}, i) = \Pr[b = b'] - 1/2$ the advantage of \mathcal{A} in guessing b in the above experiment. For every non-uniform polynomial time adversary \mathcal{A} there exists a negligible function v such that $Adv(1^{\lambda}, \mathcal{A}, i) \leq v(\lambda)$ for all $\lambda \in \mathbb{N}$.

Conference acronym 'XX, tbd, tbd tbd

We will also be interested in applying the evaluation algorithm on *all* inputs. Given a DMPF (Gen, Eval₀, Eval₁), we denote by FullEval_i an algorithm which computes $Eval_i$ on every input x. Hence, $FullEval_i$ receives only a key k_i as input.

2.3 Batch Code

We introduce batch code and probabilistic batch code, which can be used to construct DMPF.

Definition 3 (Batch Code[7]). An (N, M, t, m)-batch code over alphabet Σ is given by a pair of efficient algorithms (Encode, Decode) such that:

- Encode($x \in \Sigma^N$) \to (C_1, C_2, \dots, C_m): Any string $x \in \Sigma^N$ is encoded into an m-tuple of strings $C_1, C_2, \dots C_m \in \Sigma^*$ (called buckets) of total length M.
- Decode(I, C₁, C₂, · · · , C_m) → {x[i]}_{i∈I}: On input a set I of t distinct indices in [N] and m buckets, recover t coordinates of x indexed by I by reading at most one coordinate from each of the m buckets.

An (N, M, t, m)-batch code can be viewed as an (N, m)-bipartite graph G = (U, V, E) where each edge $(u_i, v_j) \in E$ corresponds to Encode assigning x[i] to the bucket C_j , while it is guaranteed that any subset $S \subseteq U$ such that |S| = t has a perfect matching to V. Yaxin: Add example instantiation (random regular bipartite graph) and explain it is not efficient.

Definition 4 (Probabilistic Batch Code (PBC)[1]). An (N, M, t, m, ϵ) -probabilistic batch code over alphabet Σ is a randomized (N, M, t, m)-batch code that for any string x and any set I of t distinct indices in [N],

$$\Pr[\mathsf{Decode}_r(I, \mathsf{Encode}_r(x)) \to \{x[i]\}_{i \in I}] = 1 - \epsilon$$

where the probability is taken over the public randomness r and private randomness of Encode and Decode algorithms.

We mention Cuckoo hashing algorithm[8] as a concrete instantiation of PBC[1].

w-way cuckoo hashing. Given t balls, m buckets, and w independent hash functions h_1, h_2, \cdots, h_w mapping each ball to a random bucket, allocates all balls to the buckets such that each bucket contains at most one ball through the following process:

- 1. Choose an arbitrary unallocated ball *b*.
- 2. Choose a random hash function h_i compute the bucket index $h_i(b)$. If this bucket is empty, then allocate b to this bucket and go to step 1. If this bucket is not empty and filled with ball b', then evict b', allocate b to this bucket set b' the current unallocated ball, and repeat step 2.

The algorithm should be given a fixed amount of time to run, or equipped with a loop detection process to guarantee termination. Yaxin: Add asymptotic and empirical parameters.

The balls, buckets and hash functions can be viewed as a w-regular (t,m)-bipartite graph G=(U,V,E) where each left node has w neighbors, and each edge $(u_i,v_j)\in E$ corresponds to $h_l(i)=j$ for some $1\leq l\leq w$. In this graph representation the w-way cuckoo hashing essentially computes a perfect matching from U to V. Therefore one can construct a PBC from cuckoo hashing.

Construction 1 (PBC from cuckoo hashing). Given w-way cuckoo hashing as a sub-procedure allocating t balls to m buckets with failure probability ϵ , an (N, wN, t, m, ϵ) -PBC is as follows:

- Encode_r $(x \in \Sigma^N) \to (C_1, \dots, C_m)$: Use r to determine w independent random hash functions $h_1, h_2, \dots h_w$ that maps from [N] to [m]. Initialize C_1, \dots, C_m to be empty. For each $i \in [N]$, append x[i] to $C_{h_i(i)}$ for $1 \le j \le w$.
- Decode_r $(I, C_1, \dots, C_m) \to \{x[i]\}_{i \in I}$: Determine h_1, \dots, h_w as in Encode. For I of size t, allocate I to [m] using w-way cuckoo hashing. For each $i \in I$, fetch x[i] from C_j where i is allocated to j.

2.4 Construction of DMPF from DPF basing on PBC

We display the construction of DMPF from black-box usage of DPF basing on PBC with appropriate parameters, which has been discussed in previous literature[2, 4].

Construction 2 (DMPF from DPF). Given DPF for ... and an (N, M, t, m, ϵ) -PBC with alphabet $\Sigma = \mathbb{G}$,

- Gen(1^{λ} , $\hat{f}_{A,B}$) \rightarrow (k_0 , k_1): Suppose $A = \{\alpha_1, \dots, \alpha_t\}$ and $B = \{\beta_1, \dots, \beta_t\}$. Let $TT \in \mathbb{G}^N$ be the truth table of $\hat{f}_{A,B}$. Compute Encode(TT) \rightarrow (C_1, \dots, C_m). Then run Decode(A, C_1, \dots, C_m) to determine a perfect matching from A to $\{C_1, \dots, C_m\}$. For $1 \le i \le m$, let $f_i : [|C_i|] \rightarrow \mathbb{G}$ be the following:
 - If C_i is assigned none of A by the perfect matching, then set f_i to be the all-zero function.
 - If exactly one α_j of A is assigned to the lth position of C_i , then set f_i to be the point function that outputs β_j on l and 0 elsewhere.

For $1 \leq i \leq m$, invoke DPF.Gen $(1^{\lambda}, f_i) \rightarrow (k_0^i, k_1^i)$. Set $(k_0, k_1) = (\{k_0^i\}_{i \in [m]}, \{k_1^i\}_{i \in [m]})$.

• Eval_b $(k_b, x) \rightarrow y_b$: Follow Encode(TT) to determine the positions $l_{j_1}, l_{j_2}, \dots, l_{j_s}$ such that the xth entry of TT is sent to the l_{j_i} -th position of C_{j_i} . Compute $y_b = \sum_{i=1}^s DPF$. Eval_b $(k_b^{j_i}, l_i)$.

2.5 Oblivious Key-Value Stores

DEFINITION 5 (OBLIVIOUS KEY-VALUE STORES (OKVS)[5, 9]). An Oblivious Key-Value Stores scheme is a pair of randomized algorithms (Encode_r, Decode_r) with respect to a statistical security parameter λ_{stat} and a computational security parameter λ , a randomness space $\{0,1\}^K$, a key space K, a value space V, input length n and output length m(n). The algorithms are of the following syntax:

- Encode_r({(k₁, v₁), (k₂, v₂), · · · , (k_n, v_n)}) → P: On input n key-value pairs with distinct keys, the encode algorithm with randomness r in the randomness space outputs an encoding P ∈ V^m ∪ ⊥.
- Decode_r(P, k) → v: On input an encoding from V^m and a key k ∈ K, output a value v.

We require the scheme to satisfy

- Correctness: For every $S \in (\mathcal{K} \times \mathcal{V})^n$, $\Pr_{r \leftarrow \{0,1\}^K} [\mathsf{Encode}_r(S) = \bot] \le 2^{-\lambda_{\mathsf{stat}}}$.
- **Obliviousness:** Given any distinct key sets $\{k_1^0, k_2^0, \dots, k_n^0\}$ and $\{k_1^1, k_2^1, \dots, k_n^1\}$ that are different, if they are paired with

Notes for New Constructions of DMPF Conference acronym 'XX, tbd, tbd

random values then their encodings are computationally indistinguishable, i.e.,

$$\begin{split} & \{r, \mathsf{Encode}_r(\{(k_1^0, v_1), \cdots, (k_n^0, v_n)\})\}_{v_1, \cdots, v_n \leftarrow \mathcal{V}, r \leftarrow \{0, 1\}^K} \\ &\approx_{\mathcal{C}} \{r, \mathsf{Encode}_r(\{(k_1^1, v_1), \cdots, (k_n^1, v_n)\})\}_{v_1, \cdots, v_n \leftarrow \mathcal{V}, r \leftarrow \{0, 1\}^K} \end{split}$$

One can obtain a linear OKVS if in addition require:

• Linearity: There exists a function family $\{\text{row}_r : \mathcal{K} \to \mathcal{V}^m\}_{r \in \{0,1\}^K}$ such that $\mathsf{Decode}_r(P,k) = \langle \mathsf{row}_r(k), P \rangle$.

The Encode process for a linear OKVS is the process of sampling a random P from the set of solutions of the linear system $\{\langle \mathsf{row}_r(k_i), P \rangle = v_i\}_{1 \le i \le n}$.

We evaluate an OKVS scheme by its encoding size (output length m), encoding time and decoding time. We stress the following two (linear) OKVS constructions:

Construction 3 (Polynomial). Suppose $\mathcal{K} = \mathcal{V} = \mathbb{F}$ is a field. Set

- Encode($\{(k_i, v_i)\}_{1 \le i \le n}$) $\to P$ where P is the coefficients of a (n-1)-degree \mathbb{F} -polynomial g_P that $g_P(k_i) = v_i$ for $1 \le i \le n$.
- Decode $(P, k) \rightarrow q_P(k)$.

The polynomial OKVS possesses an optimal encoding size m = n, but the Encode process is a polynomial interpolation which is only known to be achieved in time $O(n \log^2 n)$. The time for a single decoding is O(n) and that for batched decodings is (amortized) $O(\log^2 n)$.

An alternative construction that has near optimal encoding size but much better running time is as follows.

Construction 4 (3-Hash Garbled Cuckoo Table (3H-GCT)[5, 9]). Suppose $\mathcal{V} = \mathbb{F}$ is a field. Set $\operatorname{row}_r(k) := \operatorname{row}_r^{\operatorname{sparse}}(k) || \operatorname{row}_r^{\operatorname{dense}}(k)$ where $\operatorname{row}_r^{\operatorname{sparse}}$ outputs a uniformly random weight-w vector in $\{0,1\}^{m_1}$, and $\operatorname{row}_r^{\operatorname{dense}}(k)$ outputs a short dense vector in \mathbb{F}^{m_2} .

- Encode($\{(k_i, v_i)\}_{1 \le i \le n}$) \rightarrow P where P is solved from the system $\{\langle \mathsf{row}_r(k_i), P \rangle = v_i\}_{1 \le i \le n}$ using the triangulation algorithm in [9].
- Decode $(P, k) \rightarrow \langle row_r(k), P \rangle$.

This OKVS construction features a linear encoding time, constant decoding time while having a linear encoding size.

TBD: Carefully (!) recompute the comparison table for OKVS and insert $\,$

We take w=3, the most common option that outruns other choices of w in terms of running time. Restating the conclusion in [9]: given n and λ_{stat} , the choices of e and \hat{g} are $e=1.223+\frac{\lambda_{\text{stat}}+9.2}{4.144n^{0.55}}$ and $\hat{g}=\frac{\lambda_{\text{stat}}}{\log_2(en)}$.

TBD: mention some connections to cuckoo hashing

3 NEW DMPF CONSTRUCTIONS

In this section, we display two new constructions of DMPF that follow the same construction paradigm shown in fig. 1.

We begin by introducing the DMPF paradigm in fig. 1, which is based on the idea of the DPF construction in [3]. Each key $k_b(b=0,1)$ generated by $\mathrm{Gen}(\hat{f}_{A,B})$ can span a height-n (n is the input length of $\hat{f}_{A,B}$) complete binary tree T_b (call it the evaluation tree), with which party b can evaluate the input $x=x_1\cdots x_n$ by starting from the root of this tree, on the ith layer going left if $x_i=0$ and

going right if $x_i = 1$, until reaching a leaf node then computing the result according to this leaf node.

Each node of this tree is associated with a λ -bit seed and a l-bit sign. For a parent node on the ith layer with seed sd and sign sig, its children's seeds and signs are generated by PRG(sd) \oplus Correction, where the Correction is determined by the parent node's position, its sign sig and a correction word $CW^{(i)}$ associated with that layer (computed by the method Correct()). On a leaf node on the last layer, its seed sd will generate a random element in the output group, which will be corrected by adding a Correction determined by the leaf node's position, its sign and the last correction word $CW^{(n+1)}$ (computed by the method ConvCorrect()).

Call any path from the root a leaf corresponding to an input string in A an accepting path. To force the correctness, we maintain the following invariance on the evaluation trees T_0 , T_1 of the two parties:

- If a node is not on any accepting path, then T₀ and T₁ assign to it with the same seed and sign.
- If a node is on an accepting path, then T_0 and T_1 assign to it with different signs that controls the corrections on its children (or on the output if the node is on the last layer).

The paradigm contains four methods (GenCW, GenConvCW, Correct, ConvCorrect) and the sign length l to be determined by different constructions. We make the following restrictions on the methods in order to guarantee the invariance on the evaluation trees:

 $\mathsf{M}(\bar{x},\mathsf{sign},CW) = \sum_{i=1}^{l} \mathsf{sign}[i] \cdot \mathsf{M}(\bar{x},0^{i-1}0^{l-i},CW)$ for all $\mathsf{M} \in \{\mathsf{Correct},\mathsf{ConvCorrect}\}$, input \bar{x} and CW.

3.1 Big-State DMPF

TBD: explain

Conference acronym 'XX, tbd, tbd tbd

```
Public parameters:
The t-point function family \{f_{A,B}\} with t an upper
bound of the number of nonzero points, input domain [N] = \{0,1\}^n and the output
group G.
Suppose there is a public PRG G: \{0,1\}^{\lambda} \to \{0,1\}^{2\lambda+2l}. Parse G = G_0 || G_1 to the left half and right half.
Suppose there is a public PRG G_{convert}: \{0,1\}^{\lambda} \to \mathbb{G}.
procedure Gen(1^{\lambda}, \hat{f}_{A,B})
     Denote A = (\alpha_1, \dots, \alpha_t) in lexicographical order, B = (\beta_1, \dots, \beta_t). If |A| < t, extend A to size-t with arbitrary \{0, 1\}^n strings and B
     For 0 \le i \le n-1, let A^{(i)} denote the sorted and deduplicated list of i-bit prefixes of strings in A. Specifically, A^{(0)} = [\epsilon].

        return CW.
end procedure
procedure GENCONVCW(A, B, \{\text{seed}_b^{(n)}, \text{sign}_b^{(n)}\})
Sample a list CW of t random \mathbb{G}-elements.
        for k = 1 to |A| do
               \Delta g \leftarrow G_{\text{convert}}(\text{seed}_0^{(n)}[k]) - G_{\text{convert}}(\text{seed}_1^{(n)}[k]).
               CW[k] \leftarrow (-1)^{\operatorname{sign}_0^{(n)}[k][k]} (\Delta q - B[k])
        end for
        return CW.
end procedure
procedure Correct(\bar{x}, sign, CW)
        return C_{\mathsf{seed}} \| C_{\mathsf{sign}^0} \| C_{\mathsf{sign}^1} \leftarrow \sum_{i=1}^t \mathsf{sign}[i] \cdot CW[i], where
C_{\text{sign}^0} and C_{\text{sign}^1} are \tilde{t}-bit.
end procedure
 \begin{array}{c} \mathbf{procedure} \ \mathsf{ConvCorrect}(x, \mathsf{sign}, CW) \\ \mathbf{return} \ \sum_{i=1}^t \mathsf{sign}[i] \cdot CW[i]. \\ \mathbf{end} \ \mathbf{procedure} \end{array}
```

Figure 2: The parameter l and methods' setting that turns the paradigm of DMPF in fig. 1 into the big-state DMPF.

3.2 Batch-Code DMPF

display the batch-code DMPF

3.3 OKVS-based DMPF

TBD: explain

3.4 Comparison

Comparison table dependent to PRG & F-MUL(list the formulas?) analyze tradeoff distributed gen advantage

3.5 Distributed Key Generation

4 APPLICATIONS

4.1 PCG for OLE from Ring-LPN

Characterize parameters show nonregular optimization plug in new DMPF and show overall optimization

4.2 PSI-WCA

plug in new DMPF and analyze advantage interval plug in distributed gen

4.3 Heavy-hitters

private heavy-hitter or parallel ORAM?

5 ACKNOWLEDGMENTS
